# Research Institute

Thought leadership from Credit Suisse Research  
and the world's foremost experts

## Preface

Since 2010, the Credit Suisse Research Institute's Global Wealth Report has been the leading reference on global household wealth. It contains the most comprehensive and up-to-date findings on global wealth across the entire wealth spectrum – from the very base of the "wealth pyramid," capturing 3.5 billion adults with wealth below USD 10,000, to those at the apex of the wealth pyramid, who account for a small part of the world's population, but yet own a significant share of its wealth.

Research for the Credit Suisse Research Institute's Global Wealth Databook has been undertaken on behalf of the Credit Suisse Research Institute by Professors Anthony Shorrocks and Jim Davies, recognized authorities on this topic and the architects and principal authors of "Personal Wealth from a Global Perspective," Oxford University Press, 2008. Dr. Rodrigo Lluberas has also been a very significant contributor to the project.

The aim of the Credit Suisse Research Institute's Global Wealth project is to provide the best available estimates of the wealth holdings of households around the world for the period since the year 2000. While the Global Wealth Report highlights the main findings of our study, the Databook underlines the extent of our analysis. More importantly, it sets out in detail the data employed in our Global Wealth project, the methodology used to calculate estimates of wealth and how this may differ from other reports in this field.

The Global Wealth Databook provides detailed information on the evolution of household wealth levels through the period 2000 to mid-2017 at both the regional and country levels. It presents our estimates on the distribution of wealth for over 200 countries. This year's Databook presents findings on the Millennials' wealth position and provides a comparison with earlier generations.

**Estimating the pattern of global household wealth**

- Coverage of wealth levels data
- Household balance sheet and financial balance sheet sources
- Survey sources
- Changes in asset prices and exchange rates 2016–2017, selected countries
- Wealth shares for countries with wealth distribution data

**Household wealth levels, 2000–2017**

- Country details
- Population by country (thousands)
- Number of adults by country (thousands)
- Wealth estimates by country 2000–2017
- Components of wealth per adult in USD, by region and year
- Components of wealth as percentage of gross wealth, by region and year
- Changes in household wealth 2016–2017, selected countries

**Estimating the distribution of global wealth**

- Wealth pattern within countries, 2017
- Wealth pattern by region, 2017
- Membership of top wealth groups for selected countries, 2017
- Percentage membership of global wealth deciles and top percentiles by country of residence, 2017
- Main gains and losses in global wealth distribution, 2016–2017
- High net worth individuals by country and region, 2017

**Wealth and the Millennials**

- Percent of adult population aged 20–29 by country
- Wealth characteristics per adult by age, selected OECD countries, USD
- Student debt and wealth characteristics per adult by age, selected OECD countries
- Mean assets and debt of US adults, 1992–2013 (USD 2017)
- Percentage of Forbes global billionaires by age group
- Mean wealth of Forbes billionaires by age group, 2003–2017 (billions of current USD)
- Average annual returns and interest rates by cohort, USA, Europe and World, 1970–2016

**Composition of wealth portfolios**

- Assets and debts as percentage of gross household wealth for selected countries by year
- Percentage composition of gross household financial wealth, by country and year

**Region and country focus**

- Summary details for regions and selected countries, 2017
- Wealth per adult (in USD) at current and constant exchange rates, for regions and selected countries, 2000–2017
- Total wealth (in USD bn) at current and constant exchange rates, for regions and selected countries, 2000–2017
- Composition of wealth per adult for regions and selected countries, 2017
- Wealth shares and minimum wealth of deciles and top percentiles for regions and selected countries, 2017
- Distribution of wealth for regions and selected countries, 2017

# 1. Estimating the pattern of global household wealth

## 1.1 Introduction

We provide estimates of the wealth holdings of households around the world for each year since 2000. More specifically, we are interested in the distribution within and across nations of individual net worth, defined as the marketable value of financial assets plus non-financial assets (principally housing and land) less debts. No country in the world has a single comprehensive source of information on personal wealth, and many low and middle income countries have little direct evidence of any kind. However, a growing number of countries – including China and India as well many high income countries – have relevant data from a variety of different sources which we are able to exploit in order to achieve our objective.

The procedure involves three main steps, the first two of which follow the structure first set out in Davies et al. (2008, 2011). (See also Davies et al., forthcoming.) The first step establishes the average level of wealth for each country. The best source of data for this purpose is household balance sheet (HBS) data, which are now provided by 48 countries, although 25 of these countries cover only financial assets and debts. An additional four countries have household survey data from which wealth levels can be calculated. Together these countries cover 65% of the global population and 96% of total global wealth. The results are supplemented by econometric techniques, which generate estimates of the level of wealth in countries that lack direct information for one or more years.

The second step involves constructing the pattern of wealth holdings within nations. We use direct data on the distribution of wealth for 31 countries. Inspection of data for these countries suggests a relationship between wealth distribution and income distribution, which can be exploited in order to provide a rough estimate of wealth distribution for 137 other countries, which have data on income distribution but not on wealth ownership.

It is well known that the traditional sources of wealth distribution data are unlikely to provide an accurate picture of wealth ownership in the top tail of the distribution for most countries. To overcome this deficiency, the third step makes use of the information in the Forbes world list of billionaires to adjust the wealth distribution pattern in the highest wealth ranges.

Implementing these procedures leaves 44 countries for which it is difficult to estimate either the level of household wealth or the distribution of wealth, or both. Usually the countries concerned are small (e.g. Andorra, Bermuda, Guatemala, Monaco) or semi-detached from the global economy (e.g. Afghanistan, Cuba, North Korea). For our estimates of the pattern of global wealth, we assign these countries the average level and distribution of the region and income class to which they belong. This is done in preference to omitting the countries altogether, which would implicitly assume that their pattern of wealth holdings matches the world average. However, checks indicate that excluding these nations from the global picture makes little difference to the results.

Table 2-1 lists the 215 countries in the world along with some summary details. Note that China and India are treated as separate regions due to the size of their populations.

The following sections describe the estimation procedures in more detail. Two other general points should be mentioned at the outset. First, we use official exchange rates throughout to convert currencies to our standard measure of value, which is US dollars at the time in question. In international comparisons of consumption or income it is common to convert currencies using purchasing power parity (PPP) exchange rates, which take account of local prices, especially for non-traded services. However, in all countries a large share of personal wealth is owned by households in the top few percentiles of the distribution, who tend to be internationally mobile

and to move their assets across borders with significant frequency. For such people, the prevailing foreign currency rate is most relevant for international comparisons. So, there is a stronger case for using official exchange rates in studies of global wealth.

The second issue concerns the appropriate unit of analysis. A case can be made for basing the analysis on households or families. However, personal assets and debts are typically owned (or owed) by named individuals, and may be retained by those individuals if they leave the family. Furthermore, even though some household assets, such as housing, provide communal benefits, it is unusual for household members to have an equal say in the management of assets, or to share equally in the proceeds if the asset is sold. Membership of households can be quite fluid (for example, with respect to older children living away from home) and the pattern of household structure varies markedly across countries. For all these reasons – plus the practical consideration that the number of households is unknown in most countries – we prefer to base our analysis on individuals rather than household or family units. More specifically, since children have little formal or actual wealth ownership, we focus on wealth ownership by adults, defined to be individuals aged 20 or above.

## 1.2 Household balance sheet data

The most reliable source of information on household wealth is household balance sheet (HBS) data. As shown in Table 1-1, “complete” financial and non-financial “real” balance sheet data are available for 23 countries for at least one year. These are predominantly high income countries, the exceptions being the Mexico and South Africa, which fall within the upper middle income category according to World Bank. The data are described as complete if financial assets, liabilities and non-financial assets are all adequately covered. Another 25 countries have financial balance sheets, but no details of real assets. This group contains nine upper middle income countries and six lower middle income countries, and hence is less biased towards the rich world. The sources of these data are recorded in Table 1-2.

Europe and North America, and OECD countries in particular, are well represented among countries with HBS data, but coverage is sparse in Africa, Asia and Latin America. Fortunately, survey evidence on wealth is available for the largest developing countries – China, India and Indonesia – which compensates to some extent for this deficiency. Although only financial HBS data are available for Russia, complete HBS data are available for the Czech Republic and financial data are recorded for nine other former socialist countries in Europe.

## 1.3 Household survey data

Information on assets and debts is collected in nationally representative surveys undertaken in an increasing number of countries (see Table 1-3 for our current list and sources). For four countries this is the only data we have, and we use it to estimate wealth levels (with a correction for financial assets explained in the next section) as well as distributions. Data on wealth obtained from household surveys vary in quality, due to the sampling and non-sampling problems faced by all sample surveys. The high skewness of wealth distributions makes sampling error important. Non-sampling error is also a problem due to differential response rates – above some level wealthier households are less likely to participate – and under-reporting, especially of financial assets. Both of these problems make it difficult to obtain an accurate picture of the upper tail of the wealth distribution. To compensate, wealthier households are over-sampled in an increasing number of surveys, such as the US Survey of Consumer Finances and similar surveys in Canada, Germany, Spain, and several other EU countries. Over-sampling at the upper end is not routinely adopted by the developing countries which include asset information in their household surveys, but the reported response rates are much higher than in developed countries, and the sample sizes are large.

The US Survey of Consumer Finance is sufficiently well designed to capture most household wealth, but this is atypical. In particular, surveys usually yield lower totals for financial assets compared with HBS data. However, surveys generally do remarkably well for owner-occupied housing, which is the main component of non-financial assets (see Davies and Shorrocks,

2000, p. 630). Our methodology recognizes the general under-reporting of financial assets in surveys and attempts to correct this deficiency.

Other features of the survey evidence from developing countries capture important real differences. Very high shares of non-financial wealth are found for the two low-income countries in our sample, India and Indonesia, reflecting both the importance of land and agricultural assets and the relative lack of access of the rural population to financial services. On the other hand, the share of non-financial assets in China is relatively modest, in part because urban land is not privately owned. In addition, there has been rapid accumulation of financial assets by Chinese households in recent years. On average, debts are low in India and Indonesia, although debt problems of the poor are of course of concern in those countries.

For countries which have both HBS and survey data, we give priority to the HBS figures. The HBS estimates typically use a country's wealth survey results as one input, but also take account of other sources of information and should therefore dominate wealth survey estimates in quality. However, this does not ensure that HBS data are error-free.

#### 1.4 Estimating the level and composition of wealth for other countries

For countries lacking direct data on wealth, we use standard econometric techniques to estimate per capita wealth levels from the 52 countries with HBS or survey data in at least one year. Data availability limits the number of countries that can be included in this procedure. However, we are able to employ a theoretically attractive model that yields observed or estimated wealth values for 171 countries, which collectively cover 97% of the world's population in 2017. There is a trade-off here between coverage and reliability. Alternative sets of explanatory variables could achieve greater country coverage, but not without compromising the quality of the regression estimates.

Separate regressions are run for financial assets, non-financial assets and liabilities. As errors in the three equations are likely to be correlated, the seemingly unrelated regressions (SUR) technique due to Zellner (1962) is applied, but only to financial assets and liabilities, since there are fewer observations for non-financial assets. The independent variables selected are as listed in Davies et al., (forthcoming). In particular, we include a dummy for cases where the data source is a survey rather than HBS data. This turns out to be negative and highly significant in the financial assets regression, indicating that the average level of financial assets tends to be much lower when the data derive from sample surveys. We use this result to adjust upwards the value of financial assets in the wealth level estimates for China, India, Indonesia, and Uruguay. We also include region-income dummies to capture any common fixed effects at the region-income level, and year dummies to control for shocks – like the recent financial crisis – or time trends that affect the world as a whole.

The resulting estimates of net worth per adult and the three components are reported in Table 2-4 for the years 2000 to 2017. HBS data are used where available (see Table 1-1); corrected survey data are used for China, India, Indonesia, and Uruguay in specific years. Financial assets and liabilities are estimated for 119 countries, and non-financial assets for 144 countries in at least one year using the regressions described above.

There remain 44 countries containing 3% of the global adult population without an estimate of wealth per adult. In order to generate wealth figures for regions and for the world as a whole, we assigned to each of these countries the mean wealth per adult of the corresponding region (six categories) and income class (four categories). This imputation is admittedly crude, but better than simply disregarding the excluded countries, which would implicitly assume (incorrectly) that the countries concerned are representative of their region or the world.

For a few countries, including the United States, wealth levels are available for the most recent years, including the first quarter of 2017. In order to obtain estimates of net worth per adult and its components we update the most recent available figures using, where available, house price growth for non-financial assets, market capitalization for financial assets and GDP per capita growth for debts (see Table 1-4). Our projections are based on estimated relationships between

these variables and the corresponding asset/debt totals in preceding years, rather than on proportionality. For countries without information on house prices and market capitalization, recent growth of GDP per capita is used to project net worth per adult forwards to mid-2017.

## 1.5 Wealth distribution within countries

An analysis of the global pattern of wealth holdings by individuals requires information on the distribution of wealth within countries. Direct observations on wealth distribution across households or individuals are available for 31 countries. The number of survey years we have varies across countries. Summary details are reported in Table 1-5 using a common template, which gives the shares of the top 10%, 5%, 1%, together with other distributional information in the form of cumulated shares of wealth (i.e. Lorenz curve ordinates.)

The distributional data have certain fairly standard features. The unit of analysis is usually a household or family, but is in a few cases the (adult) individual. Household sample surveys are employed in almost all countries. The exceptions are the Nordic countries (Denmark, Finland, Norway and Sweden), which use data from tax and other registers covering the entire population. For all other countries, the wealth shares of the top groups are expected to be understated because wealthy households are less likely to respond, and because the financial assets that are of greater importance to the wealthy – for example, equities and bonds – are especially likely to be under-reported. Even in the U.S. Survey of Consumer Finance, where sophisticated measures are taken to counteract these problems, the sampling frame excludes the “Forbes 400” richest families, so that the extreme upper tail is not captured, by design. And in those countries using register data there can be difficulties due to valuation problems, for example in connection with pension assets and life insurance.

The summary details reported in Table 1-5 show a great deal of distributional information, but there are some empty cells. Estimates for the empty cells were generated by a revised version of the Shorrocks-Wan ungrouping program, which constructs a synthetic sample conforming exactly to any set of Lorenz values derived from a positive variable (Shorrocks and Wan, 2009). Where countries have some wealth distribution data, Lorenz curves for missing years are estimated by interpolation or by projection forwards or backwards.

For most countries lacking direct wealth distribution data, the pattern of wealth distribution was constructed from information on income distribution, based on the view that wealth inequality is likely to be highly correlated with income inequality across countries. Income distribution data for 236 countries was derived from the World Income Inequality Database, and the ungrouping program was used to generate all the Lorenz curve values required for the same template applied to wealth distribution.

For the 31 countries which have data on both wealth and income distribution, the Lorenz curves for wealth are everywhere lower than for income, indicating that wealth is more unequally distributed than income. We calculate the Gini coefficient values for both income and wealth and then estimate the missing Lorenz curves for wealth by scaling down the Lorenz curves for income by the median ratio of income to wealth Ginis.

To generate regional and global wealth patterns, to each country lacking income distribution data we assign the average (adult population weighted) wealth distribution pattern for the corresponding region and income class. This again was done in preference to simply disregarding the countries concerned.

## 1.6 Assembling the global distribution of wealth

To construct the global distribution of wealth, the level of wealth for each country was combined with details of its wealth pattern. Specifically, the ungrouping program was applied to each country to generate a set of synthetic sample values and sample weights consistent with the (estimated or imputed) wealth distribution, with the sample weights representing approximately 10,000 adults in the bottom 90% of the distribution, 1,000 adults in the top decile, and 100 adults in the top percentile. The wealth sample values were then scaled up to match the mean

wealth of the respective country, and merged into a single world dataset comprising between 1.1 million and 1.4 million observations for each year. The complete global sample may be processed in a variety of ways, for example to obtain the minimum wealth and the wealth share of each percentile in the global distribution of wealth. The distribution within regions may also be calculated, along with the number of representatives of each country in any given global wealth percentile.

### 1.7 Adjusting the upper wealth tail

The survey data from which most of our wealth distribution estimates are derived tend to under-represent the wealthiest groups and to omit ultra-high net worth individuals. This deficiency does not affect our estimates of average wealth levels around the world, since these are determined by other methods. It does imply that the shares of the top percentile and top decile are likely to err on the low side unless adjustments are made to the upper tail. We would also not expect to generate accurate predictions of the number and value of holdings of high net worth individuals.

We tackle this problem by exploiting well-known statistical regularities in the top wealth tail and by making use of information on the wealth holdings of named individuals revealed in the rich list data reported by Forbes magazine and other publications. As described in more detail in Section 3, we use the number of billionaires reported by Forbes to fit a Pareto distribution to the upper tail of 56 countries. The revised top tail values in the synthetic sample were then replaced by the new estimates, and the resulting sample for each country was re-scaled to match the mean wealth value. This sequence was repeated until the process converged, typically after a few rounds. The overall global weighted sample still contains between 1.1 and 1.3 million observations, typically representing about 100, 1,000 or 10,000 adults. The adjusted sample can be used to produce improved estimates of the true wealth pattern within countries, regions and the world. The minimum sample size of 100 allows reliable estimates of the number and value of wealth holdings up to USD 100 million at the regional and global level. Estimates above USD 100 million are obtained from projecting the Pareto distribution forward.

A further recent refinement allows us to pool the Forbes data for every year this century (currently 17 years). This produces more reliable wealth distribution estimates and enables us to produce a wealth sample for each year since 2000. The resulting data allow the trend in wealth inequality within countries and regions to be identified.

### 1.8 Concluding remarks

While the study of global household wealth is still at an early stage, enormous progress has been achieved in recent years. Data on the level of wealth are improving in quality and are available for more countries. New household wealth surveys have begun in many countries, including a sizeable number within the Eurozone orchestrated by the ECB. More needs to be done to improve the quality and frequency of wealth data, and to make the data available for a greater number of countries. In the meantime, we will continue to try to fill the gaps in the estimates of wealth level by country and to improve the estimates of wealth distribution within countries. In future, some revisions to our estimates are inevitable. Nevertheless, we are confident that the broad trends revealed in the Credit Suisse Global Wealth Report for 2017 will remain substantially intact.

## 2. Household wealth levels, 2000–2017

### 2.1 Introduction

As explained in the previous chapter, we aim to determine the level and distribution of household wealth across the world. The first stage in this process is to estimate the average level of household wealth and its core components for every country and every year since 2000.

Table 2-1 identifies 211 countries in 2017 and reports some core variables, including the classification by region, by income class according to the World Bank, and our assessment of the quality of wealth data. Population figures are available for all countries and years and are reported in Table 2-2. Figures for the number of adults, i.e. individuals aged 20 or above, are also available for most countries and years. Where the data are not reported elsewhere, we estimate the number of adults by assuming that the adult ratio is the (population weighted) average for the corresponding region and income class. The results are summarized in Table 2-3. Tables 2-2 and 2-3 reflect new population estimates by the United Nations which are sometimes very different from previous figures. The 2016 population of the United Arab Emirates, for example, is now assessed to be 9,335,000 compared to the figure of 5,240,000 given a year ago. For the world as a whole the revisions raise population by 2.1% and the number of adults by 2.4%.

The procedure outlined in Chapter 1 describes the three ways in which wealth levels data are assembled: direct estimates via national household balance sheets (HBS) or household surveys; regression estimates using likely correlated variables; and imputations based on the region-income class average. In practice, the situation is slightly more complicated because some countries have direct observations for, say, financial wealth, but require non-financial wealth to be estimated. The timeliness of direct data is greatly improved nowadays. For financial wealth at least, direct estimates for the first quarter of 2017 were available for 37 countries: Australia, Austria, Belgium, Bulgaria, Canada, Chile, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Italy, Japan, Korea, Latvia, Lithuania, Luxembourg, Malta, Netherlands, New Zealand, Norway, Poland, Portugal, Romania, Singapore, Slovakia, Slovenia, Spain, Sweden, Turkey, the United Kingdom and the United States. These countries account for 77% of global wealth in 2017. In contrast, regression-based estimates are impossible for many countries in recent years because data is missing on core regressors. In these situations, wealth estimates are obtained by taking the figure for the most recent year and updating using subsequent movements in stock market indices, house price indices, or – if nothing better is available – growth of GDP.

In Table 2-1, we do our best to summarize the quality of wealth data for each country on a five-point scale. A country gets five points, and a good rating if it has complete HBS data, and either wealth distribution data or a good basis for estimating the shape of the wealth distribution. A satisfactory rating and four points go to countries that would get a good rating except that their HBS data does not cover non-financial assets. These countries must have a full set of independent variables allowing regression-based estimates of non-financial assets. Countries without any HBS data but with a household wealth survey or other wealth distribution data (from estate tax or wealth tax sources) get a fair rating and three points. A poor rating (two points) goes to countries without HBS or wealth distribution data, but having a full set of independent variables allowing estimation of their wealth levels. If some independent variables are missing but the regressions can still be performed, the rating is very poor (one point).

In Table 2-1, there are 44 countries for which wealth data quality is not assessed. These are the countries for which we have no sensible basis for estimating wealth. In calculating the regional and global wealth figures, we assign these countries the region-income class average; but the separate country data are not reported in the later tables.

## 2.2 Household wealth levels 2000–2017

Table 2-4 summarizes information on household wealth this century for 171 countries, five regions (excluding China and India), and the world as a whole. The data refer to end-year values during the period 2000–2017 and to mid-year values for 2016 and 2017.

Most of the column content is self-explanatory. The last column indicates the estimation method used for the wealth levels, grouped into five categories. Most figures up to 2008 are labeled as either (1) "HBS", indicating data from official household balance sheets, (2) "survey data," or (3) "regression," referring to estimated values based on wealth regressions. When multiple methods are employed (e.g. for financial assets and non-financial assets), we report either "HBS" or "survey data" as appropriate. Two labels are typically reported for recent years. "Updated HBS" and "Updated regression" mean HBS data (respectively, regression estimates) updated using market capitalization growth for financial assets, house prices for non-financial assets and GDP per capita growth for debts. For countries lacking information on house prices or market capitalization, GDP per capita growth was used to project net worth per adult forward to the years 2010–2017.

Wealth estimates for recent years are subject to future revision as statistical agencies release more data. Wealth estimates for earlier periods should be less prone to change. As a rough guide, we expect that our wealth estimates prior to 2010 are not likely to change much in the future. However, statistical agencies occasionally make significant revisions to their historical data series – reflecting altered definitions of categories, or improved valuations, for example. When this happens, we are obliged to respect the new figures, and this can have repercussions for the wealth estimates of other countries, given the methods we employ. This year revisions to the UN population estimates have had an immediate and obvious impact on our estimates of wealth per adult. This has been compounded by new data on the level of non-financial assets in China, India and Russia, which has led us to revise wealth per adult upwards in each of these countries. In addition, our methods are constantly being refined in response to new developments at the frontier of research, which can also affect the historical data, although mainly for countries with little hard evidence on wealth, and hence more reliant on the techniques used to derive our estimates.

## 2.3 Wealth trends 2000–2017

From the data reported for individual years, time series can be assembled for a number of important wealth variables. Table 2-5 provides examples for the world and for each region. They show that wealth per adult has grown from USD 31,451 to 56,541 over the period 2000–2017, an average growth rate of 3.6% per annum. Most of this growth occurred before the financial crisis. In the period since 2007 average wealth has stagnated in the world outside China and North America. However, the restrained performance in recent years is largely due to appreciation of the USD. When measured at constant exchange rates, wealth has grown at a consistent, albeit modest, rate during the whole post-crisis period.

Table 2-5 provides similar details regarding the relative importance over time of the three main subcomponents of household wealth: financial assets, non-financial assets (principally housing and land) and debts. At the turn of the century, financial assets accounted for 56% of gross household assets. This share fell until 2008, when it briefly touched 50%. Since that time non-financial assets have shown little growth worldwide, in contrast to financial wealth, which has grown robustly. As a consequence, the share of financial wealth recovered to 55% by 2015, almost the same division of the portfolio as in 2000, and has remained about the same level since. Expressed as a proportion of household net worth, debt has moved in the opposite direction, and within a relatively narrow range. Globally, household debt rose from 14% of gross wealth in 2000 to 16% in 2008, and has since declined to 13%, below the level at the start of the century.

Finally, Table 2-7 extracts information on changes in household wealth in the 12 months to mid-2017. The United States continued its remarkable unbroken spell since the financial crisis with a gain of USD 8.5 trillion. Japan was the biggest loser, shedding USD 1.6 trillion due to depreciation against the US dollar.

**Table 2-1: Country details**

## 3. Estimating the distribution of global wealth

### 3.1 Comparison with data from rich lists

Our method of estimating global personal wealth is essentially a bottom-up approach. It begins by establishing the average level of wealth in different countries onto which we graft the pattern of wealth holding derived from household surveys and other sources. Although sample surveys do not formally exclude high net worth (HNW) individuals with net assets above USD 1 million, they tend to be under-represented, and their wealth holdings are likely to be undervalued. The same is true to a greater extent of ultra-high net worth (UHNW) individuals with net assets above USD 50 million. In fact, the US Survey of Consumer Finances – which otherwise does an excellent job in the upper tail of wealth distribution – explicitly omits the 400 wealthiest families from its sampling frame. Evidence suggests that other countries capture an even smaller fraction of individuals in high wealth categories. So further analysis and appropriate adjustments are required in order to construct plausible estimates of the number of wealthy individuals and the size of their holdings.

In order to proceed, we exploit the fact that the top tail of wealth distribution is usually well approximated by the Pareto distribution, which produces a straight line graph when the logarithm of the number of persons above wealth level  $w$  is plotted against the logarithm of  $w$ . Our data yield a close fit to the Pareto distribution in the wealth range from USD 250,000 to USD 5 million. Above USD 5 million the relationship begins to break down, and the correspondence weakens further above USD 50 million, as expected given the limitations of the data sources and the lumpiness caused when each sample observation represents at least 100 adults. However, it still seems reasonable to use a fitted Pareto line to estimate the number of individuals in the highest echelons of the wealth distribution.

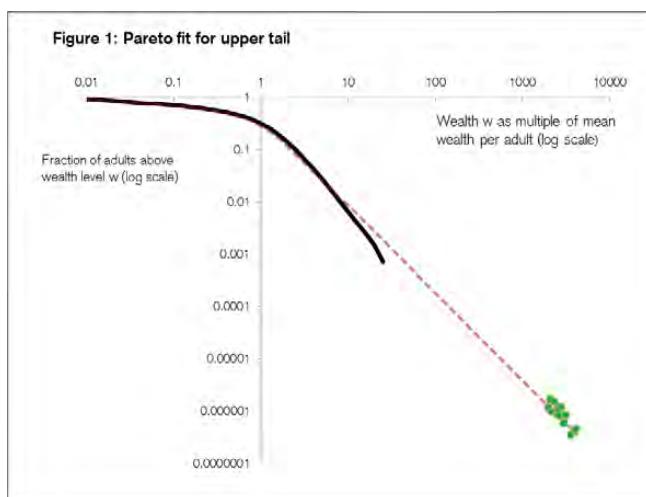

To determine the precise features of the top wealth tail, we rely heavily on the rich list data provided by Forbes and other sources. We make particular use of the number of billionaires reported by Forbes, since the data are available for many years and are broadly comparable across countries. We recognise that rich list data have limitations. The valuations of individual wealth holdings are dominated by financial assets, especially equity holdings in public companies traded in international markets. For practical reasons, less attention is given to non-financial assets apart from major real estate holdings and trophy assets, such as expensive yachts. Even less is known – and hence recorded – about personal debts. Some people cooperate enthusiastically with those compiling the lists; others jealously guard their privacy. There are also different country listings for nationals and residents, which is especially evident for India, for instance. The true beneficial ownership within families adds further complications. Assigning the wealth recorded for Bill Gates, for example, to all family members might well result in several (unequal) billionaire holdings, so the number of billionaires would increase in this instance. In other cases, reassigning the family wealth would reduce all the individual holdings below the billionaire threshold. For all these reasons, rich list data should be treated with caution. At the same time, the broad patterns and trends are informative, and they provide the best available source of information at the apex of global wealth distribution.

### 3.2 Adjusting the wealth pattern in the top tail

To mitigate some of the problems associated with small numbers of billionaires, we disregard countries that have recorded small numbers of billionaires in the Forbes list over the years. About 50 countries survive the cut. A further level of refinement involves converting the number of Forbes billionaires – which we assume refers to billionaire families – into the equivalent number of high wealth adults. Our early attempts to absorb the Forbes data used the data for a single year and identified the Pareto distribution which could be grafted onto the upper tail in order that the new distribution is consistent with the reported number of billionaires. Replacing

the initial sample observations in the top tail with the fitted Pareto values typically changes the sample mean. So the sample values were then scaled (usually down) in order to restore consistency with the correct sample mean, and the steps repeated until the process converged, typically in a few rounds.

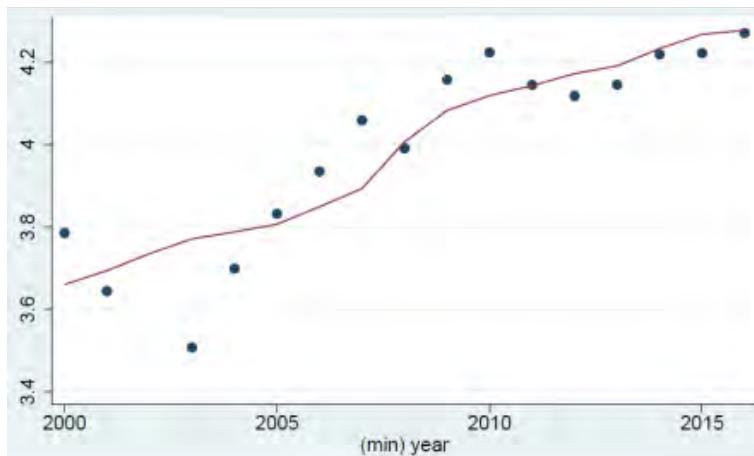

While this is an adequate method of constructing the wealth distribution for a single year, the estimates may be sensitive to relatively small changes in the Forbes data, and trends in inequality over time may be difficult to identify with any degree of confidence. To mitigate these problems we now implement two further refinements. First, we modify the way that the Pareto tail is plotted so that the Forbes data can be pooled for the entire period since 2000. This is achieved by plotting the logarithm of the *fraction* of adults above a given wealth level  $w$  on the vertical axis and using the horizontal axis to denote wealth  $w$  expressed as a *multiple of mean wealth*, again on a logarithmic scale. The curve generated by the wealth sample is now unchanged if the sample is replicated or if all wealth values are scaled up or down by the same factor. Its form depends only on the degree of inequality, as captured by the Lorenz curve. And the modification allows all the Forbes points to be plotted on the same graph – as illustrated in Figure 1 for data for the United Kingdom – regardless of how fast the adult population or mean wealth have changed over time.

Source: Original estimates; see text for explanation of methods

The second refinement this year is to make use of all the Forbes data for each country, rather than just the total number of billionaires in a particular year. Specifically, we assemble information on the fraction of adults with wealth exceeding USD 1 billion, USD 1.1 billion, USD 1.2 billion, etc. (all expressed as multiples of mean wealth) and then estimate the minimum wealth of the top .0001% of wealth holders using a fitted Pareto line like that portrayed in Figure 1. For each country, this generates a sequence of values corresponding to each for which there is sufficient data. These would conform to a horizontal line if inequality was unchanged over the whole period. More usually, there may be deviations from the horizontal over time, which may be due to a number of factors. We attempt to control for these factors by regressing the minimum wealth values against the share of financial assets in total wealth and a time trend, with a possible structural break in 2007, which the pattern for many countries suggests may be appropriate.

Figure 2 displays the results for China. While the share of financial wealth appears to have some impact, the dominant feature is an upward shift over time in the minimum wealth of the top 0.0001% with little or no structural break in 2007: in other words the pattern in China suggests a strong shift towards increasing inequality over the course of this century. When estimates of minimum wealth are missing for some of the years, we use the fitted values to complete the time series. Otherwise we retain the value obtained directly from the Forbes data.

**Figure 2: Minimum wealth of top 0.0001% as multiple of mean wealth: China**

Source: Original estimates; see text for explanation of methods

The final step in our procedure fits a Pareto top tail to the wealth distribution consistent with the estimate of the minimum wealth of the top 0.0001%. The sample values in the top tail are then replaced by the values obtained using the fitted Pareto curve.

### 3.3 Features of the global wealth distribution

Application of the top tail adjustment results in a synthetic sample containing between 1.1 and 1.3 million observations for each year since 2000, with each observation representing approximately 10,000 adults at lower wealth levels and 100 adults at the top end. These samples can then be processed to generate summary data on the wealth pattern within countries, regions and the world.

Table 3-1 reports figures for individual countries, and Table 3-2 provides more detail at the regional level. The results allow us to visualize the global wealth distribution in the form of a wealth pyramid which places adults in one of four wealth bands: under USD 10,000; between USD 10,000 and USD 100,000; between USD 100,000 and USD 1 million; and over USD 1 million. The base level of the pyramid contains 3.5 million adults, or 70% of the global population, but accounts for only 2.7% of global wealth. In contrast, dollar millionaires comprise 0.7% of all adults, but collectively own 46% of all assets. For adults with wealth exceeding USD 100,000 and USD 1 million, Table 3-3 provides further summary information for individual countries.

Combining the samples for all countries allows the features of the global distribution of wealth to be identified, including, for instance, the minimum wealth of each percentile (i.e. 1% group) worldwide and the share of total wealth owned by this group. To be among the wealthiest half of the world in mid-2017, Table 3-4 shows that an adult needs only USD 3,580 in assets, once debts have been subtracted. However, a person needs at least USD 76,750 to belong to the top 10% of global wealth holders and USD 770,370 to be a member of the top 1%. Taken together, the bottom half of the global population own less than 1% of total wealth. In sharp contrast, the richest decile hold 88% of the world's wealth, and the top percentile alone account for 50% of global assets.

The decile breakdown by regions has a number of interesting features. China dominates the upper middle section of the global wealth distribution, accounting for 40% of members of deciles 6–9. In contrast, residents of India are heavily concentrated in the lower wealth strata, accounting for over a quarter of people in the bottom half of the distribution.

Table 3-4 shows that residents of Latin America are spread quite evenly across the global wealth spectrum. The Asia-Pacific region (excluding China and India) mimics the global pattern more closely still, although the apparent uniformity of the Asia-Pacific region masks a substantial degree of polarization between high-income countries, such as Hong Kong, Japan and Singapore, and lower income countries, such as Bangladesh, Indonesia, Pakistan and Vietnam. In fact, when high-income countries are excluded from the Asia-Pacific group, the wealth pattern within the remaining countries resembles that of India. Residents of Africa are also heavily concentrated at the bottom end of the wealth spectrum: half of all African adults are found in the bottom two global wealth deciles. In sharp contrast, North America and Europe are heavily skewed toward the top tail, together accounting for 60% of adults in the top 10%, and 73% of those in the top percentile.

Table 3-5 lists the countries that have gained or lost the most number of members of the global top decile and percentile during the year to mid-2017. It also reports changes in the number of millionaires during the past twelve months.

### 3.4 The number of high and ultra-high net worth individuals

Apart from the rich lists, which cover a relatively small number of named individuals, there is a scarcity of information on wealth holdings above USD 1 million. Survey details are patchy at best, and official statistics based on tax returns are often inadequate given the complexity of wealth ownership arrangements. Our method of adjusting the top tail using rich list data pooled over several years helps to bridge this gap. Smoothing the wealth distribution at the top end by means of a Pareto curve fitted to the data for each country then produces plausible estimates of the global pattern of asset holdings in the high net worth (HNW) category from USD 1 million to USD 50 million, and in the ultra-high net worth (UHNW) range from USD 50 million upwards.

Table 3-6 reports the numbers for mid-2017. While the base of the wealth pyramid is occupied by people from all countries at various stages of their lifecycles, HNW and UHNW individuals are heavily concentrated in particular regions and countries, and tend to share more similar lifestyles, participating in the same global markets for luxury goods, even when they reside in different continents. The wealth portfolios of these individuals are also likely to be more similar, with more of a focus on financial assets and, in particular, equity holdings in public companies traded in international markets.

For mid-2017, we estimate that 35.9 million HNW adults have wealth between USD 1 million and USD 50 million, of whom the vast majority (31.4 million) fall within the USD 1–5 million range. North America accounts for the greatest number, significantly above Europe, which in turn hosts nearly double the number in Asia-Pacific countries, excluding China and India. China, Latin America, India and Africa together account for less than 8% of all HNW individuals.

UHNW individuals with net assets above USD 50 million now number 148,200 worldwide by our calculations. Among individual countries, the United States leads with 49% of UHNW adults. China has recently moved into second place, but is a distant second with only 12% of the total membership.

**Table 3-1: Wealth pattern within countries, 2017**

Country	Adults	Mean wealth per adult	Median wealth per adult	Distribution of adults (%) by wealth range (USD)				Gini

## 4. Wealth of the Millennials

### 4.1 Introduction

The “Millennials” – people who came of age after the turn of the century – have had a run of bad luck, most clearly in developed markets. Capital losses in the global financial crisis of 2008–2009 and high subsequent unemployment dealt them serious blows. Add rising student debt in several countries, tighter mortgage rules after 2008, higher house prices, increased income inequality, less access to pensions and lower income mobility and you have conditions that have held back wealth accumulation by the Millennials in many countries. While in emerging markets, it appears that trends have been somewhat more positive (see the Credit Suisse Emerging Market Survey 2017), on the whole, the Millennials have not been a lucky generation.

The Millennials’ challenges seem to have been most evident in North America, but the ripples have extended to Europe and elsewhere. They contrast with the good fortune experienced by the baby boomers, born in large numbers between 1945 and 1964, whose wealth was boosted by a range of factors including large windfalls due to property and share price increases (D’Arcy and Gardiner, 2017). The millennial cohort is smaller as a percentage of the total adult population than the baby boomers were at the same age. Normally it is good to belong to a smaller cohort: there is less congestion in school and less competition with peers for jobs and homes. So, one may ask why the millennials are not a fortunate cohort. Did the financial crisis and its fallout just swamp the advantage of being in a small cohort? Or is there more to it?

Some commentators have mentioned the shadow cast by the baby boomers in developed countries. The boomers are now aged about 50 to 70 – their peak wealth years. They occupy many of the top jobs and much of the housing, especially at the higher end. Some Millennials feel that their own progress is being held up as they wait for the boomers to vacate. Cohort analysis seems to have been turned on its head: the big cohort is now the lucky one.

The comparison between Millennials and boomers is not entirely fair. All cohorts tend to have relatively high wealth when aged 50–70, and young people always struggle to settle in the labor market, establish families and buy homes. The boomers also experienced setbacks: the stagnation of the 1970s, high mortgage rates in the 1980s, and high inflation for a couple of decades. However, the Millennials are doing less well than their parents at the same age, with respect to incomes, home ownership and other dimensions of well-being (Leatherby, 2017). In this chapter we compare various aspects of wealth holding by Millennials with their counterparts in previous generations.

### 4.2 Demographics

Part of the explanation for the challenges of the Millennials in many countries may be that the cohort is small, but not that small after all. The Millennials are the children of the boomers. There were many baby boomers and altogether they had many children – sometimes referred to as the “echo generation.”

Table 4-1 shows the fraction of the population between ages 20 and 29 in different regions from 1980 onwards. For the world as a whole, the trend is downwards, but the decline slowed after the year 2000, with the Millennials coming of age. Furthermore, the trend was not uniformly downward. Between 2000 and 2010, the fraction aged 20 to 29 rose in Africa and India, and was roughly constant in North America. Among G7 countries and the BRICS, it rose in Germany, Russia, South Africa and the United Kingdom. So, in some key countries and regions, young people born in the 1980s formed a mini population wave, likely exacerbating their labor market and other problems as they came of age (Fry, 2015, and Leatherby, 2017). However, the opposite happened in the Asia-Pacific region, China and Latin America. Also, the percentage aged 20–29 did not rise between 2010 and 2017 in any region or major country, so the second wave of Millennials was smaller than the first. On the basis of demographics alone, therefore, the younger Millennials may expect an easier time than their slightly older contemporaries.

### 4.3 Assets and debts of the Millennials

Table 4-2 provides a breakdown by age for various wealth characteristics in the developed markets of France, Germany, Italy, the United Kingdom and the United States. Families have been split into their adult members, and each adult assigned an equal share of the family's wealth. Thus, the numbers refer to the wealth of the family in which the adult lives, rather than the amount that legally belongs to the individual, which is not given in the source data. This distinction should be borne in mind when interpreting our results, especially for the youngest group, many of whom still live with their parents.

The table reminds us that income and wealth both generally increase with age – certainly for the average individual, but also usually in cross-section data (there are exceptions – see Credit Suisse Emerging Consumer Survey 2016). The share of financial assets also rises once young millennial adults have left the parental nest. Non-financial assets – of which owner-occupied homes are the most important – decline in importance with age. For many people, the first priority is to buy a house, with financial assets being built up later. This pattern helps to explain why the high and rising house prices seen in many countries since the year 2000 have been a special problem for the Millennials.

Financial assets are especially important in the United Kingdom, peaking at 61% of total assets in the 50–59 age group. This reflects the fact that the UK data include the value of all non-state pensions. The US data include only defined contribution pension plans – hence the lower figure of 41% for the same group. Data for the other countries does not include employer-based pensions of any kind, although, in all the countries shown, individuals' private retirement savings are counted.

According to the IMF, state pensions in advanced economies are expected to replace just 20% of per capita income by 2060, compared with 35% today. Also, fewer workers are now covered by employer-based pensions than in the past, and defined benefit pensions are declining fast. Cribb et al. (2016) report that only 10% of UK workers in the private sector born in the 1980s have a defined benefit pension plan, compared to 40% of those born in the 1960s at the same age. So it is increasingly important for people to save for retirement on their own account. The share of financial assets in total assets will need to rise in most countries in the future compared to what is seen in Table 4-2. This is especially true for the Millennials, who will likely face the added challenge of higher contributions and taxes required to fund state pensions and other benefits for the baby boom cohort in their retirement.

As a fraction of both total assets and income, debt rises from age 20 onwards, and then falls steadily with age in all the countries shown in Table 4-2. Acquiring mortgage debt and then paying it off explains much of this pattern. Apart from the United Kingdom, where debt exceeds two years' income for those aged 30–40, the ratios of average debt to assets or income do not appear alarming. However, the averages conceal the fact that there is a minority for whom debt loads are a problem. That minority is largest in the most indebted age groups, which means those in the 30–39 year age group in each country.

Student loans have been an increasingly important component of debt in a number of countries. The trend is particularly striking in the United States and is also evident in Germany (see Table 4-3). In the United States, 37% of those aged 20–29 in 2013 had some student debt, which accounted for 18% of the total debt of that age group. In Germany, 12% of those in the same age group had student debt and it accounted for about 6% of total debt.

The rise in student debt is partly due to higher fees. Total tuition fees rose 63% between 2006 and 2016 in the US for example (Leatherby, 2017). But it also reflects the fact that the Millennials are more educated than preceding cohorts. For instance, the percentage of 25–34 year-olds with tertiary education in OECD countries rose from about 15% in 1970 to 26% in 2000 and 43% in 2016 (OECD, 2017). This greater educational attainment may help to ease the Millennials' labor market difficulties. However, although average rates of return to college and university have held up fairly well (Abel and Deitz, 2014; Patrinos, 2016), this is largely because lower wages for less-educated workers have reduced the opportunity cost of tertiary education. Acquiring more education in order to overcome the "millennial disadvantage" is a strategy that will reap rewards for a minority of high achievers and those specializing in areas in high demand – high tech, finance

and so on. But it seems likely that for most university-educated Millennials the outcome will be job opportunities and wages no better than their parents', achieved by a dint of more costly education.

Some Millennials have received financial help from their family to pay for higher education and for house purchases. Others may have inherited wealth or stand to do so in the future (D'Arcy and Gardiner 2017). Of those aged 20–39, only about 10%–15% of adults have inherited in the United States, France and Germany (Table 4-3). Many more will inherit later – by age 70 about 30%–40% of adults have inherited in these countries, and in the United Kingdom the number is close to 50% (Karagiannaki and Hills, 2013, Table 5.3). The amounts involved are sizeable. In the countries shown in Table 4-3, of individuals aged 30–39 who had already inherited, reported inheritances averaged 40% of their current total assets. Some respondents forget about small transfers that they have received, and some may be unaware of likely future bequests. Even taking that into account, the surveys suggest it is unlikely that more than 50% of a typical cohort stand to inherit at any point in their lives. But those who do inherit will receive substantial amounts, on average. With the Millennials' parents' wealth having been boosted by high house prices and the booming stock market of recent years, the expectation that half of the Millennials will not inherit while the other half receive relatively large amounts is a source of higher inequality for that generation compared with earlier cohorts.

#### 4.4 Entrepreneurship

Of 1,031 US adults between the ages of 18 and 34 surveyed in 2014, 67% would like to start their own business and 37% would like to work for themselves (Bentley University, 2014). And the evidence, both in the US and internationally, is that Millennials are starting more businesses than did the baby boomers, plus doing it when they are younger (BNP Paribas, 2016). But the official statistics show that only 2% of Millennials in the United States are self-employed, versus 8% of Generation Xers (those born between 1965 and 1980) and baby boomers. And entrepreneurship, as measured by the fraction of self-employed workers, has been declining in most OECD countries since the turn of the century. The OECD self-employment rate fell from 17.6% in 2001 to 15.8% in 2011; in the United States it dropped from 7.4% in 2001 to 6.5% in 2015. There are also big declines in some emerging market countries – a fall from 52.8% in 2001 to 33.0% between 2001 and 2015 in Turkey, for example, and a drop from 36.4% to 32.1% in Mexico. Almost the only OECD country showing an increase is the United Kingdom, where the rate rose steadily from 12.2% in 2001 to 14.9% in 2015. Sagging entrepreneurship in most countries is consistent with relatively few Millennials starting a business in this period.

What causes the apparent contradiction between Millennials' attitudes toward entrepreneurship and their actual participation in it has been considered by Thompson (2016) and Alton (2017) who identify some key factors. One is just that the cohorts are being observed at the same point in time, not at the same age. More Millennials will start businesses as they age. Another explanation is that those Millennials who have become entrepreneurs have each created more businesses than their counterparts in earlier cohorts. This may reflect their "tech savvy" and the greater ease of starting multiple businesses these days with the help of the internet. A third factor is that although many Millennials would like to start a business, for a time they were restrained by tough economic conditions. This suggests a surge in millennial entrepreneurship may occur soon or may already be taking place, as has been seen in some emerging markets, such as China and India.

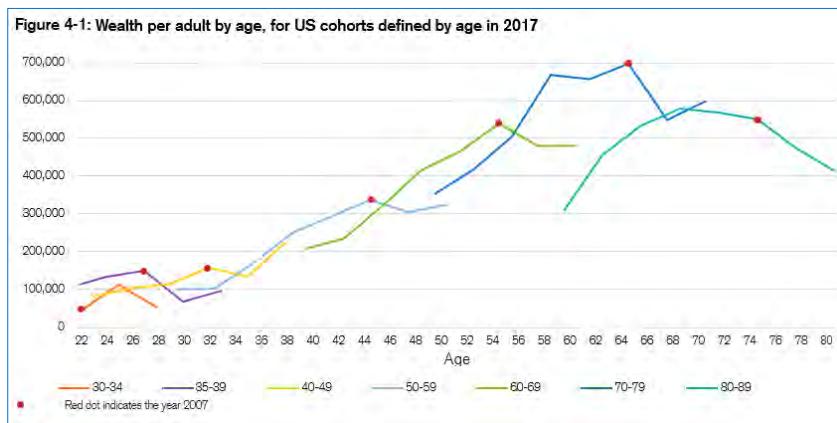

#### 4.5 Comparing cohorts

Table 4-4 shows mean assets and debts, in USD 2017, for US adults aged 20–29 and 30–39 in 1992, 1998, 2007 and 2013. Total assets increased markedly for the 20–29 year-old group between 1998 and 2007, due mostly to an increase in real assets caused by rising house prices. Real assets for 30–39 year olds also increased rapidly at that time, but mean financial assets fell in this age range, perhaps reflecting re-allocation of portfolios in response to the changing returns from real and financial assets. Things went into reverse between 2007 and 2013: real assets declined substantially for both groups and financial assets increased a little. Debt rose strongly for both groups between 1998 and 2007, but has since returned to its 1992 level.

These comparisons tell us about the experience of Generation X and the Millennials in their early adulthood. Generation X was still in its late 20s and 30s when house prices rocketed in the United States prior to the global financial crisis, and during the crisis itself. So, it as well as the first wave of Millennials had a wild roller coaster ride. They experienced not only the effects of the general rise and fall of economic activity, but also the impacts of wild swings in asset prices. Both aspects are reflected in the wealth changes seen in Table 4-4.

## 4.6 Tracking cohorts

Several countries have time series of household wealth surveys that can be used to trace the fortunes of different cohorts over time. The United States Survey of Consumer Finance (SCF), for example, has been conducted every three years since 1992. This allows us to track the wealth of a given cohort from survey to survey. Figure 4-1 displays the mean wealth of cohorts of adults grouped according to age in 2017. Overall, wealth rises with age and declines in retirement, but the damage caused by the financial crisis is evident.

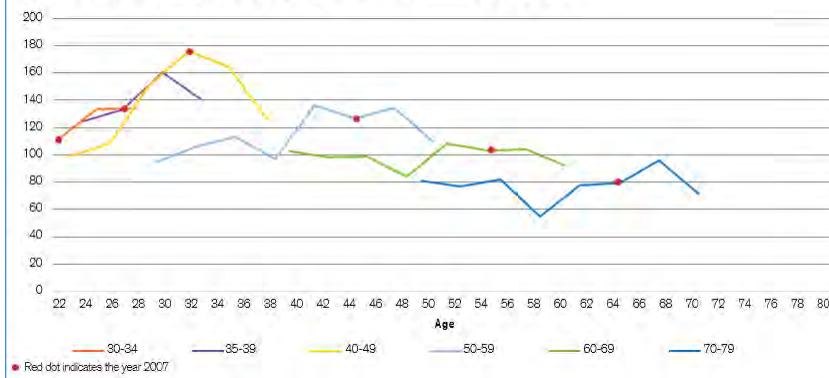

Source: Credit Suisse Global Investment Returns Yearbook 2017

Most of the (connected) age-wealth profiles not only dip after 2007, but drop below the profile of the next age group. Instead of having higher wealth at a given age than their predecessors – as has invariably been the case during the past half century or more – each of the cohorts aged from 35 to 79 had less wealth after 2007 than its immediate predecessor at the same age. The decline in wealth of most cohorts after 2007 is a “year effect,” unrelated to age or cohort. The years after 2007 were bad, and they were bad for everyone. D’Arcy and Gardiner (2017) point out that, in the UK, all the cohorts born after 1955 had less wealth in 2013 than their predecessors had just five years earlier. This is the same effect that we see in Figure 4-1 and as we have explained it is a sign of bad times, not a cohort effect. It is quite likely that a cohort that experiences bad times early in its life cycle is at a lasting disadvantage. If so, we would expect to see in the future that the Millennials do worse than their predecessors at the same age even when good times – or at least better times – appear. Unfortunately, the current economic recovery has not lasted long enough for that comparison to be made at present.

Figure 4-2 displays US age-debt ratio profiles in a similar fashion. For each cohort aged 40 or more in 2017, the debt to income ratio was higher than that of previous cohorts at all ages. The “crossing over” observed for wealth in Figure 4-1 is not seen, reflecting the fact that debts do not fall in value when houses and shares crash, as they did during the financial crisis. But, perhaps most interestingly, the pattern is interrupted for the Millennials. The debt to income ratio started out higher than earlier cohorts for those aged 35–39 in 2017, and also rose (briefly, in 2010) above earlier cohorts for those aged 30–34 in 2017. But then there was a crossing-over in 2013 for both of these cohorts, with their debt to income ratios declining below previous cohorts. This

hints that the Millennials became more cautious about debt than their predecessors due to the shock of the housing bust in the United States and the global crisis.

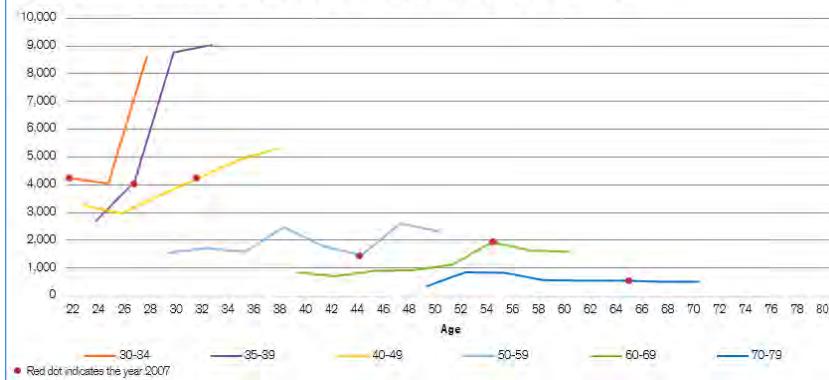

**Figure 4-2: Debt as % of income by age, for US cohorts defined by age in 2017**

Source: Credit Suisse Global Investment Returns Yearbook 2017

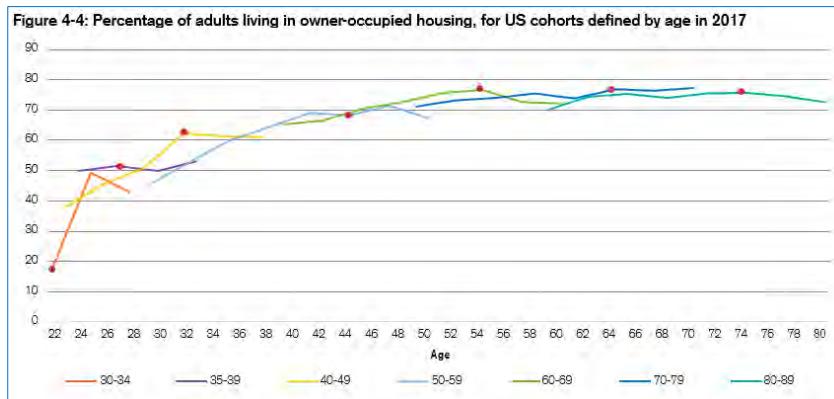

Student debt has leapt up for the most recent cohorts in the United States (Figure 4-3). The biggest increase came for the cohort aged 35–39 in 2017 – i.e. the “leading edge” of the Millennials – but those aged 30–34 in 2017 saw a further increase. As noted earlier, as a consequence, student debt now forms a substantial portion of total debt for young people in the United States.

**Figure 4-3: Student debt per adult by age, for US cohorts defined by age in 2017 (USD)**

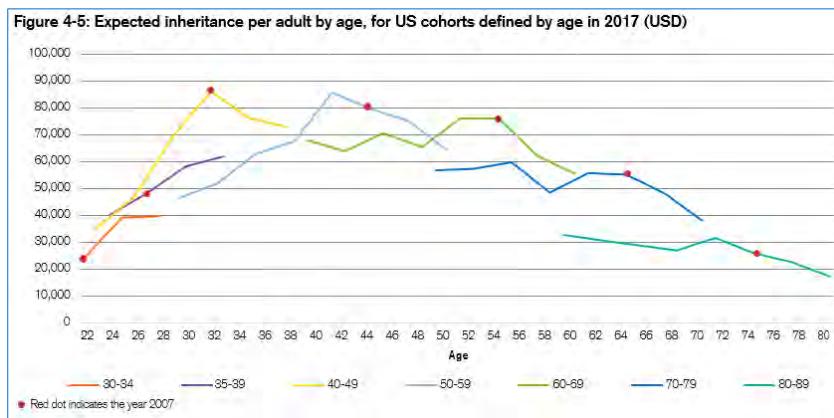

Source: Credit Suisse Global Investment Returns Yearbook 2017

The percentage of adults living in owner-occupied housing shows much more stability over cohorts (Figure 4-4). The oldest cohorts follow almost exactly the same path, but for those aged 40–49 or 35–39 in 2017, there was a higher initial fraction of home owners in successive cohorts. The financial crisis resulted in crossing-over once again, and by 2013 these cohorts slipped below previous cohorts with regard to the fraction of homeowners. The record of those aged 30–34 in 2017 is less clear cut due to an upward “blip” in home ownership recorded in the 2010 survey, which could be a statistical artefact.

Source: Credit Suisse Global Investment Returns Yearbook 2017

However, their home ownership rate in 2007 and 2013 was below previous cohorts, again suggesting a more cautious approach to home ownership prompted by the housing bust and the financial crisis. Survey evidence also suggests that US Millennials are more pessimistic about future inheritances than previous cohorts (Figure 4-5). They expect to inherit less than their immediate predecessors at the same age, perhaps because they know that their parents suffered a substantial reduction in wealth during and following the financial crisis.

Source: Credit Suisse Global Investment Returns Yearbook 2017

## 4.7 Inequality and mobility

Millennials have been affected by the general rise in income inequality in advanced economies over recent decades. In a world with constant mean income, constant inequality and no mobility, parents and children would be equally well off. If – more likely – mean income is rising, and there is some mobility, but inequality is constant, then most children will be better off than their parents. But income inequality has been rising in the United States since the mid-1970s, and while mean income has also risen considerably, median income has not increased much.

Since the mid-1970s inequality has been rising in the United States and while mean income has also risen considerably, median income has not gone up a lot. Mobility has also gone down. Fairly similar trends have been seen in other "Anglo" countries (of course with some differences). The result is that, from a situation in which a large majority of people had earnings exceeding their

parents' at the same age, we have arrived at quite a different situation. Chetty et al. (2016) find that about 90% of US children born in 1940 had earnings greater than their parents', while this ratio had fallen to 50% for children born in the 1980s. About 70% of this decline was due to the rise in inequality.

## 4.8 Billionaire Millennials

Some Millennials have become very prominent billionaires, for example the principals in Google, Facebook, Twitter, and some other internet or high tech enterprises. This raises the question of whether some Millennials, at least, have been unusually successful entrepreneurs.

There are few young billionaires on the Forbes list, but an interesting trend has emerged. In 2003 and 2005, only one person under 30 appeared on the list. This jumped to five by 2010 and to nine by 2017. The number aged 30–39 has also risen over time, but up to 2010 it did so more slowly than the total number of billionaires, so the percentage of billionaires aged below 40 fell from 5.8% in 2003 to 2.9% in 2010 (Table 4-5). However, this fraction stabilized after 2010 and was 2.8% in 2017.

In absolute terms, the number of young billionaires has risen sharply in the last several years. There were 21 billionaires aged less than 40 in 2003, and just 24 in 2010. But by 2017 the number had risen to 46. Furthermore, their mean wealth rose substantially – from USD 3.2 billion in 2010 to USD 4.1 billion in 2017 (Table 4-6). This increase in wealth was especially marked in the last two years.

The Peterson Institute has studied the origins of wealth, and the geographic/demographic profile of the Forbes billionaires (Freund, 2016). They find interesting trends in emerging market (EM) countries since 2000, especially in comparison with the developed countries. The age distribution and fraction of self-made billionaires has changed little in developed countries. But in emerging markets the fraction of self-made billionaires rose from 56% in 2001 to 79% in 2014. Meanwhile, the billionaires are younger in the emerging market countries: billionaires under the age of 50 outnumbered those over 70 in 2014. In high-income countries, on the other hand, one-third of billionaires in 2014 were over 70 and only 12% were aged less than 50. The upsurge of young, self-made billionaires in emerging markets has been seen as a sign of healthy growth and economic dynamism.

## 4.9 Rates of return and interest rates

The financial prospects of a cohort are affected by the rates of return they receive on investments and by the interest rates they face. Throughout the world, equity returns were high in both nominal and real terms during the 1980s and 1990s, providing favorable investment opportunities to baby boomers in the first half of their working lives, and also to young members of Generation X (Table 4-7). In the first decade of the new century, however, both real and nominal returns collapsed, creating quite a different investment environment for the Millennials. After 2010, returns rebounded, but not to the level seen in the 1980s and 1990s.

The interest rate story is similar to that for equity returns, but the decline in real rates began earlier, in the 1990s. Although they rebounded slightly in Europe after 2000, the decline was steady in the United States. This is significant because workers trying to acquire assets increasingly have to switch to riskier investments to get a reasonable rate of return. Real lending rates, which are also important for young people, via mortgages for example, have declined over time as well, but more slowly than deposit rates. In the United States, lending rates reached quite a low level after 2010, but in Europe they remained at 3.8%, far above the real deposit rate of 0.4%. Hence safe saving opportunities have deteriorated for young people, while borrowing has not become correspondingly cheaper.

## 4.10 Conclusion

The Millennials have not been a lucky cohort so far. They faced the rigors of the financial crisis and the high unemployment that followed in many countries, and have also been widely hammered by high and rising house prices, rising student debt and increasing inequality. Their pension

outlook is also worse than that of preceding cohorts. Some of the Millennials have prospered in spite of these difficulties, as reflected in the more positive picture we see in China and a range of other emerging markets, and the recent upsurge in the number of Forbes billionaires below the age of 40. Some have had substantial family help in paying for education and buying homes, and some stand to inherit from wealthy boomer parents in the future. But there are many Millennials who have not been so fortunate. As a result, the Millennials are not only likely to experience greater challenges in building their wealth over time, but also greater wealth inequality than previous generations.

## 5. Composition of wealth portfolios

### 5.1 Financial versus non-financial assets

We look first at the relative importance of financial versus non-financial assets in the average household portfolio. Expressed as a percentage of gross household assets, the pattern clearly differs markedly between poorer and richer countries and regions, as can be seen in Table 5-1, which shows the breakdown for the countries where we have the best data. In developing countries, for example India and Indonesia, it is not unusual for 80% or more of total assets to be held in the form of non-financial assets, including housing, farms and small business assets. This pattern is also associated with the relative under-development of financial institutions in many lower income countries.

As countries develop – and make the transition to a market economy – the importance of non-financial assets tends to decline. An interesting example is provided by China, where the share of financial assets is 45% in 2017. Another example is provided by Singapore, a country further along the development path, but still nevertheless seeing the share of financial assets in household portfolios continuing to rise – from 44% in 2000 to 56% in 2017. In the richest countries, financial assets typically account for more than half of household wealth. An important example is the United States, where 71%–73% of household assets have been held in financial form in each year since 2005 (although the share is somewhat inflated by the US practice of classifying all business equity as a financial asset).

There are interesting exceptions to this general pattern. Robust house price rises drove the share of non-financial assets above 60% in France and Italy by 2010 and it has since drifted down in those countries. The share of non-financial assets also rose in the United Kingdom, from 44% in 2000 to 53% in 2005, although it has since fallen back to 48%. In the developing world, South Africa is a strong outlier, having an exceptionally high share of financial assets: the share of 64% in 2017 exceeds that found in all G7 countries except the United States. This high share reflects, on the one hand, the advanced development of South Africa's financial institutions including its private pensions, and on the other hand, relatively low house prices.

### 5.2 Composition of financial assets

Table 5-2 provides some detail on the composition of financial assets, for a greater number of countries. It shows the breakdown into three categories: currency and deposits (liquid assets); equities (all shares and other equities held directly by households); and other financial assets. In most countries the reserves of life insurance companies and pension funds form the largest component of "other financial assets" – these reserves comprise equities and other financial assets that are in effect being held on behalf of the household sector.

The composition of financial assets differs considerably across countries. One interesting aspect is that equities held directly are not always a large component of household financial wealth, even in countries with very active financial markets. In the United Kingdom and Japan, for example, equities account for 10-15% of total financial assets. In contrast, they make up 35% of financial assets in Sweden 36% in the United States, and over 40% in Bulgaria, Estonia, Finland, Hungary, and New Zealand. To calculate the overall percentage of the household portfolio held in equities, equities held indirectly via insurance policies and pension plans would need to be added to the total of those held directly. However, this is not possible since the household balance sheet data available in most countries do not show the composition of assets held in insurance and pension reserves. If the purpose were to find out the total exposure of the household sector to stock market risk, it is also not clear that this exercise would provide the answer. Households have explicit or implicit guarantees on their rights to many insurance and

pension benefits, so that the risk characteristics of the latter may differ from those of the assets held in the reserves.

Where equities account for more of the portfolio, there is less room for liquid assets or other financial assets. The strongest negative association is between equities and other financial assets, perhaps because other financial assets are larger where private pension systems are more highly developed and may tend to crowd out privately held equities. A good example of this phenomenon is found in Australia, where only 17% of the average portfolio is in equities vs. an average of 28% for the countries in Table 5-2 showing 2016 data, but other financial assets have a share of 61%, well above the average figure of 35%. A similar pairing of below-average equities and above-average other financial assets is seen, in most years, in nine countries in Table 5-2, including France, Germany, Norway, and the United Kingdom. The opposite case, of above average equities and below average other financial assets is found in eight countries, which include some transition economies as well as Austria, Finland, and Spain. The negative association between equities and liquid assets is weaker, but shows up in countries like Japan where liquid assets are 52% of the portfolio versus 14% for equities, and at the opposite end of the scale the United States, with only 14% in liquid form versus 36% in equities.

There are also interesting differences across country types. The typical portfolio in the well-established high-income market economies has less liquid assets than average, equities at about the average level, and other financial assets somewhat above average. Emerging market countries tend to have less in both equities and other financial assets than the established high income countries, and therefore a higher share in liquid assets than seen in the typical rich country. On average, the transition countries have more in liquid assets than either the high income countries or emerging market economies, perhaps reflecting the fact that their financial systems have had less time to develop.

### 5.3 Changes over time

While the financial crisis of 2007–2008 is receding into the past, it was a landmark event for household wealth, bringing an abrupt decline in most personal fortunes and a change in household behavior and wealth performance in most countries. In light of these aspects, it is interesting to examine how the overall composition of personal wealth and, in particular, the proportion of financial assets to total household assets has changed over the past decade. A decline in the relative importance of financial assets was seen in a number of countries in 2008, for example in Denmark, Italy, Switzerland and notably China. In other countries, the credit crisis depressed both property prices and share values, so the share of financial assets was more stable; little change was seen in 2008 in the share of financial assets in the United Kingdom and the United States. Only in the Czech Republic and New Zealand did the relative size of financial assets increase appreciably in 2008.

Longer term, the share of financial assets does not often appear to change dramatically. In France, a relative increase in property prices in the period since 2000 has reduced the share from 45% to 40%, and a similar effect is seen in Italy, where the share fell from 47% to 41%. Elsewhere, however, effects generally seem to be mostly short term. The United States showed a relative decline in financial assets from 2000 to 2005, for example, but then with a booming stock market the share rebounded. Its rise was only halted temporarily by the financial crisis. The share peaked at 73% in 2014 and has now fallen back a little, to 71%, which is not much greater than its year 2000 level of 69%. Japan showed a rise in the proportion of financial assets during 2000–2006, a decline during the financial crisis, and a small subsequent increase, finishing at 61%, significantly above the 53% seen in 2000. Among major developing nations the financial asset share rose from 2000 to the early 2010s but has fallen over the last several years. In 2017, at 45% this share was the same in China as in 2000, but it was somewhat higher in 2017 than in 2000 in both India and Indonesia.

The importance of debt has also changed over the years since 2000. For many countries, including the United Kingdom and the United States, there was a significant rise in the period leading up to the financial crisis and a decline thereafter. However, this experience is not universal. In Japan, for example, the debt ratio was steady from 2000 to 2008, and in Germany it fell over that period. What is common to most OECD countries, however, is that the debt ratio

fell after the financial crisis. So where debt had not risen before the crisis, it nonetheless tended to fall afterwards – from 16% to 14% in Japan, for example, and from 15% to 13% in Germany. Contrasting post-crisis results are seen in a few high income countries where the debt ratio held steady, as in France, or even rose a little, as in Australia. Trends also differed in rapidly developing countries like China, India and Indonesia, which have seen their debt ratios rise throughout the early year of the century, seemingly unaffected by volatility in the global economy. Since 2014, debt has fallen as a fraction of gross assets in most developed countries. An exception is Switzerland, where there has been a mild increase.

#### 5.4 Conclusion

The composition of household balance sheets is an important determinant of trends in consumption and investment, and in many ways reflects the financial development of individual countries. For instance, debt as a proportion of total household assets tends to be low in developing and some transition countries because financial intermediation and property rights are underdeveloped, while debt levels in OECD countries are relatively high, reflecting a more developed financial system.

Our analysis of household balance sheets examines financial and non-financial assets and debt from a global perspective. In general, non-financial assets like housing, land and small business assets make up a relatively large proportion of household wealth in the developing world and in transition countries. While their relative importance is smaller in the high income countries there is variation. Non-financial assets are still quantitatively more important than financial assets in Australia, France, Germany, Italy and New Zealand. In contrast, financial assets form a large proportion of the household balance sheets in countries like the United States, Japan and the Netherlands.

## 6. Region and country focus

### 6.1 Introduction

Countries differ greatly in terms of their level and pattern of wealth holdings. There are also distinct differences at the regional level. It is therefore interesting to compare regional variations and trends since the year 2000, and to document the variety of country circumstances and experiences.

While data quality is generally good in the rich countries that hold most of the world's wealth, it is usually questionable elsewhere. The countries discussed in this section are all interesting in their own right. But another reason for their selection is that they all have data on the mean level of household wealth and a reasonable way to estimate the distribution of wealth across the population.

The accompanying tables collate information on wealth holdings for each of the regions and countries. Some of the core data is summarized in Table 6-1. Table 6-2 reports wealth per adult measured in current US dollars and in "constant dollars" by which is meant the average USD exchange rate for the period 2010-2017. Table 6-3 provides similar information for aggregate household wealth measured in trillion US dollars. Table 6-4 shows the composition of wealth for the most recent year for which figures are available. For each region and country, the wealth share of each decile and the top percentiles is recorded in Table 6-5, along with the minimum wealth needed to belong to a given regional wealth quantile. Finally, Table 6-6 shows the distribution of the adult population by wealth range.

### 6.2 Mean wealth 2000–2017

Three charts are provided for each of the regions. Figure 1 plots two series for mean wealth over 2000–2017, one measured in current US dollars and the second calculated using the average USD exchange rate. The global level of wealth per adult – which amounted to USD 52,500 in 2017 – masks considerable regional variation. The average for North America in 2017 was USD 375,000 compared to USD 135,000 in Europe, USD 47,500 in the Asia-Pacific region (excluding China and India), USD 19,000 in Latin America, USD 26,900 in China, USD 4,200 in Africa and USD 6,000 in India.

All regions have recorded an increase in wealth per adult since the start of the century. If wealth is measured in local currencies, growth has been sustained and generally continuous apart from the financial crisis period when all regions except Latin America suffered a setback. If wealth is valued in current USD, the picture is somewhat different. Between 2000 and 2007, dollar depreciation raised the regional growth rates; but dollar appreciation in more recent years has had the opposite effect. As a consequence, wealth per adult in 2017 remains below its 2007 level in Africa, Europe and Latin America.

This in turn has implications for global wealth inequality. Although wealth levels in Europe and Northern America have always been far above those in other regions, particularly Africa and India, the regional imbalance appeared to be eroding during the early years of the century. Africa, India, Latin America, and most notably China, all increased their share of world wealth between 2000 and 2007, hinting at the possibility that global wealth inequality was on a long-term downward trend. The subsequent reversal of growth rates accompanied by evidence of growing wealth inequality both within and between countries suggests that falling wealth inequality may be a more distant prospect.

### 6.3 Components of personal wealth

Table 6-4 displays the breakdown of wealth per adult for each region into financial and real (non-financial) forms, as well as the average level of debt. On average internationally, financial assets now comprise 54% of gross assets, while non-financial assets account for 46% and debts amount to 13%. Financial assets are relatively more important in Japan where they represent 61% of gross assets and the United States, where they account for 71%. In developing regions, non-financial assets typically account for the bulk of household wealth: they form 69% of gross assets in Latin America and 86% of assets in India, for example.

A systematic link with the stage of development is also evident in the level of household debts expressed as a percentage of gross assets. The share is 9% in India, 8% in China and 10% in Africa, but averages 14% in the Asia-Pacific region, Europe and North America.

### 6.4 Wealth distribution

Table 6-5 shows wealth distribution for each region. Some interesting contrasts between regions are evident. More than 93% of adults in Africa own less than USD 10,000, and 92% of adults in India fall in this range. Meanwhile the fraction is 63% in China, 44% in Europe and 28% in North America. On the other hand, 26% of adults in Europe and 41% in North America have wealth above USD 100,000. The wealth distribution in both Latin America and the Asia-Pacific region closely resembles the pattern in the world as a whole, and Latin America shows 66% and Asia-Pacific 73% of all adults owning less than USD 10,000.

Among developed countries, there is substantial variation in the percentage of adults recorded in the lowest wealth ranges. Some countries report significant numbers of people in this category, while others show very few. This reflects such factors as availability of credit including student loans, as well as how many young adults live separately from their parents, making their low wealth more apparent in the survey returns.

## About the authors

**Professor Anthony Shorrocks** is Director of Global Economic Perspectives Ltd. After receiving his PhD from the London School of Economics (LSE), he taught at the LSE until 1983, when he became Professor of Economics at Essex University, serving also as Head of Department and Director of Economic Research for the British Household Panel Study. In 2001, he was appointed Director of the World Institute for Development Economics Research of the United Nations University (UNU-WIDER) in Helsinki, where he remained until 2009. He has published widely on income and wealth distribution, inequality, poverty and mobility, and was elected a Fellow of the Econometric Society in 1996. Publications include "The age-wealth relationship: A cross section and cohort analysis" (Review of Economics and Statistics 1975), "The portfolio composition of asset holdings in the United Kingdom" (Economic Journal 1982), and, with Jim Davies and others, "Assessing the quantitative importance of inheritance in the distribution of wealth" (Oxford Economic Papers 1978), "The distribution of wealth" (Handbook of Income Distribution 2000), "The world distribution of household wealth" in Personal Wealth from a Global Perspective (Oxford University Press 2008), "The global pattern of household wealth" (Journal of International Development 2009), "The Level and Distribution of Global Household Wealth" (Economic Journal 2011) and "Estimating the Level and Distribution of Global Wealth, 2000-2014" (Review of Income and Wealth, forthcoming).

**Professor Jim Davies** has been a member of the Department of Economics at the University of Western Ontario in Canada since 1977 and served as chair of the department from 1992 to 2001. He received his PhD from the London School of Economics in 1979. Jim was the director of the Economic Policy Research Institute at UWO from 2001 to 2012. In 2010, he completed a term as managing editor of the academic journal Canadian Public Policy. From 2006 to 2008, he directed an international research program on household wealth holdings at UNU-WIDER in Helsinki and edited the resulting volume, "Personal Wealth from a Global Perspective" (Oxford University Press 2008). He has authored two books and over 70 articles and chapters in books on topics ranging from tax policy to household saving and the distribution of wealth. Publications include "The Relative Impact of Inheritance and Other Factors on Economic Inequality" (Quarterly Journal of Economics 1982), "Wealth and Economic Inequality" (Oxford Handbook of Economic Inequality, Oxford University Press, 2009), and several publications on wealth authored jointly with Anthony Shorrocks and others. Jim is also the editor of "The Economics of the Distribution of Wealth," published in 2013 by Edward Elgar.

**Dr. Rodrigo Lluberas** is an Analyst at the Research department of Uruguay Central Bank. He received his PhD in Economics from Royal Holloway College, University of London and his MSc in Economics from University College London. He has been a visiting scholar at the Institute for Fiscal Studies and an Economist at Towers Watson in London. Prior to undertaking his MSc, he worked for three years as an economic analyst at Watson Wyatt Global Research Services and more recently as a research assistant at NESTA. His main areas of expertise are pensions, consumption and wealth. Rodrigo is a co-author of "Estimating the Level and Distribution of Global Wealth, 2000-2014" (Review of Income and Wealth, forthcoming).

## Additional regional disclaimers

Hong Kong: Credit Suisse (Hong Kong) Limited ("CSHK") is licensed and regulated by the Securities and Futures Commission of Hong Kong under the laws of Hong Kong, which differ from Australian laws. CSHKL does not hold an Australian financial services license (AFSL) and is exempt from the requirement to hold an AFSL under the Corporations Act 2001 (the "Act") under Class Order 03/1103 published by the ASIC in respect of financial services provided to Australian wholesale clients (within the meaning of section 761G of the Act). Research on Taiwanese securities produced by Credit Suisse AG, Taipei Securities Branch has been prepared by a registered Senior Business Person. Malaysia: Research provided to residents of Malaysia is authorized by the Head of Research for Credit Suisse Securities (Malaysia) Sdn Bhd, to whom they should direct any queries on +603 2723 2020. Singapore: This report has been prepared and issued for distribution in Singapore to institutional investors, accredited investors and expert investors (each as defined under the Financial Advisers Regulations) only, and is also distributed by Credit Suisse AG, Singapore branch to overseas investors (as defined under the Financial Advisers Regulations). By virtue of your status as an institutional investor, accredited investor, expert investor or overseas investor, Credit Suisse AG, Singapore branch is exempted from complying with certain compliance requirements under the Financial Advisers Act, Chapter 110 of Singapore (the "FAA"), the Financial Advisers Regulations and the relevant Notices and Guidelines issued thereunder, in respect of any financial advisory service which Credit Suisse AG, Singapore branch may provide to you. UAE: This information is being distributed by Credit Suisse AG (DIFC Branch), duly licensed and regulated by the Dubai Financial Services Authority ("DFSA"). Related financial services or products are only made available to Professional Clients or Market Counterparties, as defined by the DFSA, and are not intended for any other persons. Credit Suisse AG (DIFC Branch) is located on Level 9 East, The Gate Building, DIFC, Dubai, United Arab Emirates. UK: The protections made available by the Financial Conduct Authority and/or the Prudential Regulation Authority for retail clients do not apply to investments or services provided by a person outside the UK, nor will the Financial Services Compensation Scheme be available if the issuer of the investment fails to meet its obligations. To the extent communicated in the United Kingdom ("UK") or capable of having an effect in the UK, this document constitutes a financial promotion which has been approved by Credit Suisse (UK) Limited which is authorized by the Prudential Regulation Authority and regulated by the Financial Conduct Authority and the Prudential Regulation Authority for the conduct of investment business in the UK. The registered address of Credit Suisse (UK) Limited is Five Cabot Square, London, E14 4QR. Please note that the rules under the UK's Financial Services and Markets Act 2000 relating to the protection of retail clients will not be applicable to you and that any potential compensation made available to "eligible claimants" under the UK's Financial Services Compensation Scheme will also not be available to you. Tax treatment depends on the individual circumstances of each client and may be subject to changes in future EU: This report has been produced by subsidiaries and affiliates of Credit Suisse operating under its Global Markets Division and/or International Wealth Management Division.
